I²C-bus autosync deflection controller for PC monitors

TDA4857PS

FEATURES

Concept features

- Full horizontal plus vertical autosync capability
- Extended horizontal frequency range from 15 to 130 kHz
- Comprehensive set of I²C-bus driven geometry adjustments and functions, including standby mode
- Very good vertical linearity
- Moire cancellation
- Start-up and switch-off sequence for safe operation of all power components
- X-ray protection
- Flexible switched mode B+ supply function block for feedback and feed forward converter
- Internally stabilized voltage reference
- Drive signal for focus amplifier with vertical parabola waveforms
- DC controllable inputs for Extremely High Tension (EHT) compensation
- SDIP32 package.

Synchronization

- Can handle all sync signals (horizontal, vertical, composite and sync-on-video)
- Output for video clamping (leading/trailing edge selectable by I²C-bus), vertical blanking and protection blanking
- Output for fast unlock status of horizontal synchronization and blanking on grid 1 of picture tube.

Horizontal section

- I²C-bus controllable wide range linear picture position, pin unbalance and parallelogram correction via horizontal phase
- Frequency-locked loop for smooth catching of horizontal frequency
- Simple frequency preset of f_{min} and f_{max} by external resistors
- Low jitter
- Soft start for horizontal and B+ control drive signals.

Vertical section

- I²C-bus controllable vertical picture size, picture position, linearity (S-correction) and linearity balance

- Output for I²C-bus controllable vertical sawtooth and parabola (for pin unbalance and parallelogram)
- Vertical picture size independent of frequency
- Differential current outputs for DC coupling to vertical booster
- 50 to 160 Hz vertical autosync range.

East-West (EW) section

- I²C-bus controllable output for horizontal pincushion, horizontal size, corner and trapezium correction
- Optional tracking of EW drive waveform with line frequency selectable by I²C-bus.

Focus section

- I²C-bus controllable output for vertical parabola
- Vertical parabola is independent of frequency and tracks with vertical adjustments.

GENERAL DESCRIPTION

The TDA4857PS is a high performance and efficient solution for autosync monitors. All functions are controllable by the I²C-bus.

The TDA4857PS provides synchronization processing, horizontal and vertical synchronization with full autosync capability and very short settling times after mode changes. External power components are given a great deal of protection. The IC generates the drive waveforms for DC-coupled vertical boosters such as the TDA486x and TDA835x.

The TDA4857PS provides extended functions e.g. as a flexible B+ control, an extensive set of geometry control facilities and an output for vertical focus signals.

Together with the I²C-bus driven Philips TDA488x video processor family, a very advanced system solution is offered.

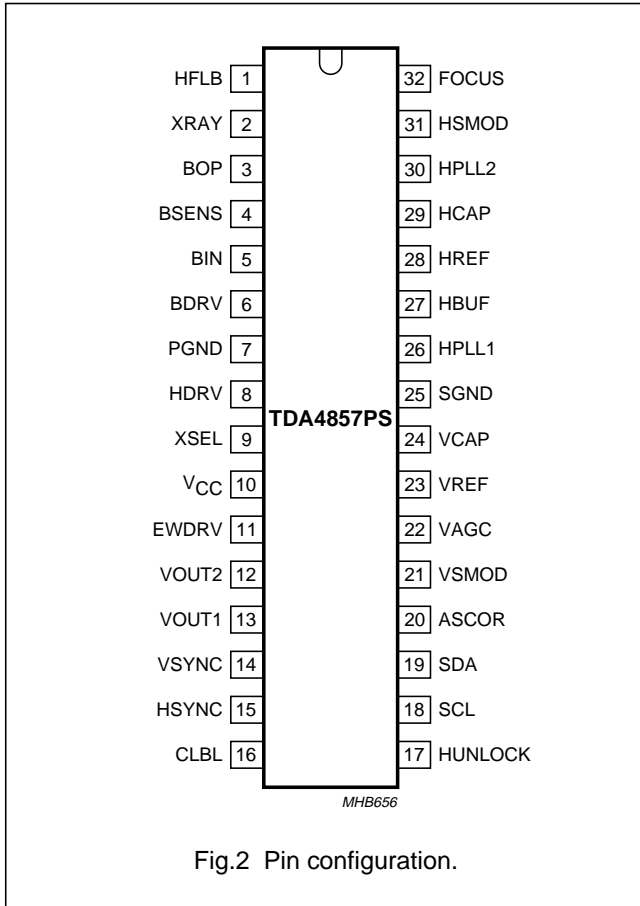

Fig.2 Pin configuration.

FUNCTIONAL DESCRIPTION

Horizontal sync separator and polarity correction

HSYNC (pin 15) is the input for horizontal synchronization signals, which can be DC-coupled TTL signals (horizontal or composite sync) and AC-coupled negative-going video sync signals. Video syncs are clamped to 1.28 V and sliced at 1.4 V. This results in a fixed absolute slicing level of 120 mV related to top sync.

For DC-coupled TTL signals the input clamping current is limited. The slicing level for TTL signals is 1.4 V.

The separated sync signal (either video or TTL) is integrated on an internal capacitor to detect and normalize the sync polarity.

Normalized horizontal sync pulses are used as input signals for the vertical sync integrator, the PLL1 phase detector and the frequency-locked loop.

Vertical sync integrator

Normalized composite sync signals from HSYNC are integrated on an internal capacitor in order to extract vertical sync pulses. The integration time is dependent on the horizontal oscillator reference current at HREF (pin 28). The integrator output directly triggers the vertical oscillator.

Vertical sync slicer and polarity correction

Vertical sync signals (TTL) applied to VSYNC (pin 14) are sliced at 1.4 V. The output signal of the sync slicer is integrated on an internal capacitor to detect and normalize the sync polarity. The output signals of vertical sync integrator and sync normalizer are disjuncted before they are fed to the vertical oscillator.

Video clamping/vertical blanking generator

The video clamping/vertical blanking signal at CLBL (pin 16) is a two-level sandcastle pulse which is especially suitable for video ICs such as the TDA488x family, but also for direct applications in video output stages.

The upper level is the video clamping pulse, which is triggered by the horizontal sync pulse. Either the leading or trailing edge can be selected by setting control bit CLAMP via the I²C-bus. The width of the video clamping pulse is determined by an internal single-shot multivibrator.

The lower level of the sandcastle pulse is the vertical blanking pulse, which is derived directly from the internal oscillator waveform. It is started by the vertical sync and stopped with the start of the vertical scan. This results in optimum vertical blanking. Two different vertical blanking times are accessible, by control bit VBLK, via the I²C-bus.

Blanking will be activated continuously if one of the following conditions is true:

- Soft start of horizontal and B+ drive [voltage at HPLL2 (pin 30) pulled down externally or by the I²C-bus]
- PLL1 is unlocked while frequency-locked loop is in search mode or if horizontal sync pulses are absent
- No horizontal flyback pulses at HFLB (pin 1)
- X-ray protection is activated
- Supply voltage at V_{CC} (pin 10) is low (see Fig.23).

Horizontal unlock blanking can be switched off, by control bit BLKDIS, via the I²C-bus while vertical blanking and protection blanking is maintained.

I²C-bus autosync deflection controller for PC monitors

TDA4857PS

Frequency-locked loop

The frequency-locked loop can lock the horizontal oscillator over a wide frequency range. This is achieved by a combined search and PLL operation. The frequency range is preset by two external resistors and the

recommended maximum ratio is $\frac{f_{\max}}{f_{\min}} = \frac{6.5}{1}$

This can, for instance, be a range from 15.625 to 90 kHz with all tolerances included.

Without a horizontal sync signal the oscillator will be free-running at f_{\min} . Any change of sync conditions is detected by the internal coincidence detector. A deviation of more than 4% between horizontal sync and oscillator frequency will switch the horizontal section into search mode. This means that PLL1 control currents are switched off immediately.

The internal frequency detector then starts tuning the oscillator. Very small DC currents at HPLL1 (pin 26) are used to perform this tuning with a well defined change rate. When coincidence between horizontal sync and oscillator frequency is detected, the search mode is first replaced by a soft-lock mode which lasts for the first part of the next vertical period. The soft-lock mode is then replaced by a normal PLL operation. This operation ensures smooth tuning and avoids fast changes of horizontal frequency during catching.

In this concept it is not allowed to load HPLL1. The frequency dependent voltage at this pin is fed internally to HBUF (pin 27) via a sample-and-hold and buffer stage. The sample-and-hold stage removes all disturbances caused by horizontal sync or composite vertical sync from the buffered voltage. An external resistor connected between pins HBUF and HREF defines the frequency range.

Out-of-lock indication (pin HUNLOCK)

Pin HUNLOCK is floating during search mode if no sync pulses are applied, or if a protection condition is true. All this can be detected by the microcontroller if a pull-up resistor is connected to its own supply voltage.

For an additional fast vertical blanking at grid 1 of the picture tube a 1 V signal referenced to ground is available at this output. The continuous protection blanking (see Section "Video clamping/vertical blanking generator") is also available at this pin. Horizontal unlock blanking can be switched off, by control bit BLKDIS via the I²C-bus, while vertical blanking is maintained.

Horizontal oscillator

The horizontal oscillator is of the relaxation type and requires a capacitor of 10 nF to be connected at HCAP (pin 29). For optimum jitter performance the value of 10 nF must not be changed.

The minimum oscillator frequency is determined by a resistor connected between pin HREF and ground. A resistor connected between pins HREF and HBUF defines the frequency range.

The reference current at pin HREF also defines the integration time constant of the vertical sync integration.

Calculation of line frequency range

The oscillator frequencies f_{\min} and f_{\max} must first be calculated. This is achieved by adding the spread of the relevant components to the highest and lowest sync frequencies $f_{\text{sync}(\min)}$ and $f_{\text{sync}(\max)}$. The oscillator is driven by the currents in R_{HREF} and R_{HBUF} .

The following example is a 31.45 to 90 kHz application:

Table 1 Calculation of total spread

spread of	for f_{\max}	for f_{\min}
IC	±3%	±5%
C_{HCAP}	±2%	±2%
$R_{\text{HREF}}, R_{\text{HBUF}}$	±2%	±2%
Total	±7%	±9%

Thus the typical frequency range of the oscillator in this example is:

$$f_{\max} = f_{\text{sync}(\max)} \times 1.07 = 96.3 \text{ kHz}$$

$$f_{\min} = \frac{f_{\text{sync}(\min)}}{1.09} = 28.9 \text{ kHz}$$

The TV mode is centred around f_{\min} with a control range of ±10%. Activation of the TV mode is only allowed between 15.625 and 35 kHz.

The resistors R_{HREF} and R_{HBUFpar} can be calculated using the following formulae:

$$R_{\text{HREF}} = \frac{78 \times \text{kHz} \times \text{k}\Omega}{f_{\min} + 0.0012 \times f_{\min}^2 [\text{kHz}]} = 2.61 \text{ k}\Omega$$

$$R_{\text{HBUFpar}} = \frac{78 \times \text{kHz} \times \text{k}\Omega}{f_{\max} + 0.0012 \times f_{\max}^2 [\text{kHz}]} = 726 \text{ }\Omega$$

I²C-bus autosync deflection controller for PC monitors

TDA4857PS

The resistor $R_{HBUFpar}$ is calculated as the value of R_{HREF} and R_{HBUF} in parallel. The formulae for R_{HBUF} also takes into account the voltage swing across this resistor

$$R_{HBUF} = \frac{R_{HREF} \times R_{HBUFpar}}{R_{HREF} - R_{HBUFpar}} \times 0.8 = 805 \Omega$$

PLL1 phase detector

The phase detector is a standard type using switched current sources, which are independent of the horizontal frequency. It compares the middle of the horizontal sync with a fixed point on the oscillator sawtooth voltage. The PLL1 loop filter is connected to HPLL1 (pin 26).

See also Section "Horizontal position adjustment and corrections".

Horizontal position adjustment and corrections

A linear adjustment of the relative phase between the horizontal sync and the oscillator sawtooth (in PLL1 loop) is achieved via register HPOS. Once adjusted, the relative phase remains constant over the whole frequency range.

Correction of pin unbalance and parallelogram is achieved by modulating the phase between the oscillator sawtooth and horizontal flyback (in loop PLL2) via registers HPARAL and HPINBAL. If those asymmetric EW corrections are performed in the deflection stage, both registers can be disconnected from the horizontal phase via control bit ACD. This does not change the output at pin ASCOR.

Horizontal moire cancellation

To achieve a cancellation of horizontal moire (also known as 'video moire'), the horizontal frequency is divided-by-two to achieve a modulation of the horizontal phase via PLL2. The amplitude is controlled by register HMOIRE. To avoid a visible structure on screen the polarity changes with half of the vertical frequency. Control bit MOD disables the moire cancellation function.

PLL2 phase detector

The PLL2 phase detector is similar to the PLL1 detector and compares the line flyback pulse at HFLB (pin 1) with the oscillator sawtooth voltage. The control currents are independent of the horizontal frequency. The PLL2 detector thus compensates for the delay in the external horizontal deflection circuit by adjusting the phase of the HDRV (pin 8) output pulse.

For the TDA4857PS external modulation of the PLL2 phase is not allowed, because this would disturb the start advance of the horizontal focus parabola.

Soft start and standby

If HPLL2 is pulled to ground by resetting the register SOFTST, the horizontal output pulses, vertical output currents and B+ control driver pulses will be inhibited. This means that HDRV (pin 8), BDRV (pin 6), VOUT1 (pin 13) and VOUT2 (pin 12) are floating in this state. If HPLL2 is pulled to ground by an external DC current, vertical output currents stay active while HDRV (pin 8) and BDRV (pin 6) are in floating state. In both cases the PLL2 and the frequency-locked loop are disabled, CLBL (pin 16) provides a continuous blanking signal and HUNLOCK (pin 17) is floating.

This option can be used for soft start, protection and power-down modes. When the HPLL2 pin is released again, an automatic soft start sequence on the horizontal drive as well as on the B+ drive output will be performed (see Figs 24 and 25).

A soft start can only be performed if the supply voltage for the IC is a minimum of 8.6 V.

The soft start timing is determined by the filter capacitor at HPLL2 (pin 30), which is charged with a constant current during soft start. If the voltage at pin 30 (HPLL2) reaches 1.1 V, the vertical output currents are enabled. At 1.7 V the horizontal driver stage generates very small output pulses. The width of these pulses increases with the voltage at HPLL2 until the final duty cycle is reached. The voltage at HPLL2 increases further and performs a soft start at BDRV (pin 6) as well. The voltage at HPLL2 continues to rise until HPLL2 enters its normal operating range. The internal charge current is now disabled. Finally PLL2 and the frequency-locked loop are activated. If both functions reach normal operation, HUNLOCK (pin 17) switches from the floating status to normal vertical blanking, and continuous blanking at CLBL (pin 16) is removed.

Output stage for line drive pulses [HDRV (pin 8)]

An open-collector output stage allows direct drive of an inverting driver transistor because of a low saturation voltage of 0.3 V at 20 mA. To protect the line deflection transistor, the output stage is disabled (floating) for a low supply voltage at V_{CC} (see Fig.23).

The duty cycle of line drive pulses is slightly dependent on the actual horizontal frequency. This ensures optimum drive conditions over the whole frequency range.

I²C-bus autosync deflection controller for PC monitors

TDA4857PS

X-ray protection

The X-ray protection input XRAY (pin 2) provides a voltage detector with a precise threshold. If the input voltage at XRAY exceeds this threshold level for a certain time then control bit SOFTST is reset, which switches the IC into protection mode. In this mode several pins are forced into defined states:

HUNLOCK (pin 17) is floating

The capacitor connected to HPLL2 (pin 30) is discharged

Horizontal output stage (HDRV) is floating

B+ control driver stage (BDRV) is floating

Vertical output stages (VOUT1 and VOUT2) are floating

CLBL provides a continuous blanking signal.

There are two different methods of restarting the IC:

1. XSEL (pin 9) is open-circuit or connected to ground. The control bit SOFTST must be set to logic 1 via the I²C-bus. The IC then returns to normal operation via soft start.
2. XSEL (pin 9) is connected to V_{CC} via an external resistor. The supply voltage of the IC must be switched off for a certain period of time before the IC can be restarted again using the standard power-on procedure.

Vertical oscillator and amplitude control

This stage is designed for fast stabilization of vertical size after changes in sync frequency conditions.

The free-running frequency $f_{fr(V)}$ is determined by the resistor R_{VREF} connected to pin 23 and the capacitor C_{VCAP} connected to pin 24. The value of R_{VREF} is not only optimized for noise and linearity performance in the whole vertical and EW section, but also influences several internal references. Therefore the value of R_{VREF} must not be changed.

Capacitor C_{VCAP} should be used to select the free-running frequency of the vertical oscillator in accordance with the

following formula: $f_{fr(V)} = \frac{1}{10.8 \times R_{VREF} \times C_{VCAP}}$

To achieve a stabilized amplitude the free-running frequency $f_{fr(V)}$, without adjustment, should be at least 10% lower than the minimum trigger frequency.

The contributions shown in Table 2 can be assumed.

Table 2 Calculation of $f_{fr(V)}$ total spread

Contributing elements	
Minimum frequency offset between $f_{fr(V)}$ and lowest trigger frequency	10%
Spread of IC	±3%
Spread of R_{VREF}	±1%
Spread of C_{VCAP}	±5%
Total	19%

Result for 50 to 160 Hz application:

$$f_{fr(V)} = \frac{50 \text{ Hz}}{1.19} = 42 \text{ Hz}$$

The AGC of the vertical oscillator can be disabled by setting control bit AGCDIS via the I²C-bus. A precise external current has to be injected into VCAP (pin 24) to obtain the correct vertical size. This special application mode can be used when the vertical sync pulses are serrated (shifted); this condition is found in some display modes, e.g. when using a 100 Hz upconverter for video signals.

Application hint: VAGC (pin 22) has a high input impedance during scan. Therefore, the pin must not be loaded externally otherwise non-linearities in the vertical output currents may occur due to the changing charge current during scan.

Adjustment of vertical size, VGA overscan and EHT compensation

The amplitude of the differential output currents at VOUT1 and VOUT2 can be adjusted via register VSIZE. Register VOVSCN can activate a +17% step in vertical size for the VGA350 mode.

VSMOD (pin 21) can be used for a DC controlled EHT compensation of vertical size by correcting the differential output currents at VOUT1 and VOUT2. The EW waveforms, vertical focus, pin unbalance and parallelogram corrections are not affected by VSMOD.

The adjustments for vertical size and vertical position also affect the waveforms of the horizontal pincushion, vertical linearity (S-correction), vertical linearity balance, focus parabola, pin unbalance and parallelogram correction. The result of this interaction is that no re-adjustment of these parameters is necessary after an adjustment of vertical picture size or position.

I²C-bus autosync deflection controller for PC monitors

TDA4857PS

Adjustment of vertical position, vertical linearity and vertical linearity balance

Register VPOS provides a DC shift at the sawtooth outputs VOUT1 and VOUT2 (pins 13 and 12) and the EW drive output EWDRV (pin 11) in such a way that the whole picture moves vertically while maintaining the correct geometry.

Register VLIN is used to adjust the amount of vertical S-correction in the output signal. This function can be switched off by control bit VSC.

Register VLINBAL is used to correct the unbalance of the vertical S-correction in the output signal. This function can be switched off by control bit VLC.

Adjustment of vertical moire cancellation

To achieve a cancellation of vertical moire (also known as 'scan moire') the vertical picture position can be modulated by half the vertical frequency. The amplitude of the modulation is controlled by register VMOIRE and can be switched off via control bit MOD.

Horizontal pincushion (including horizontal size, corner correction and trapezium correction)

EWDRV (pin 11) provides a complete EW drive waveform. The components horizontal pincushion, horizontal size, corner correction and trapezium correction are controlled by the registers HPIN, HSIZE, HCOR and HTRAP. HTRAP can be set to zero by control bit VPC.

The pincushion (EW parabola) amplitude, corner and trapezium correction track with the vertical picture size (VSIZE) and also with the adjustment for vertical picture position (VPOS). The corner correction does not track with the horizontal pincushion (HPIN).

Further the horizontal pincushion amplitude, corner and trapezium correction track with the horizontal picture size, which is adjusted via register HSIZE and the analog modulation input HSMOD.

If the DC component in the EWDRV output signal is increased via HSIZE or I_{HSMOD}, the pincushion, corner and trapezium component of the EWDRV output will be

reduced by a factor of $1 - \frac{V_{\text{HSIZE}} + V_{\text{HEHT}} \left(1 - \frac{V_{\text{HSIZE}}}{14.4 \text{ V}}\right)}{14.4}$

The value 14.4 V is a virtual voltage for calculation only. The output pin can not reach this value, but the gain (and DC bias) of the external application should be such that the horizontal deflection is reduced to zero when EWDRV reaches 14.4 V.

HSMOD can be used for a DC controlled EHT compensation by correcting horizontal size, horizontal pincushion, corner and trapezium. The control range at this pin tracks with the actual value of HSIZE. For an increasing DC component V_{HSIZE} in the EWDRV output signal, the DC component V_{HEHT} caused by I_{HSMOD} will be

reduced by a factor of $1 - \frac{V_{\text{HSIZE}}}{14.4 \text{ V}}$ as shown in the previous equation.

The whole EWDRV voltage is calculated as follows:
 $V_{\text{EWDRV}} = 1.2 \text{ V} + [V_{\text{HSIZE}} + V_{\text{HEHT}} \times f(\text{HSIZE}) + (V_{\text{HPIN}} + V_{\text{HCOR}} + V_{\text{HTRAP}}) \times g(\text{HSIZE}, \text{HSMOD})] \times h(I_{\text{HREF}})$

Where:

$$V_{\text{HEHT}} = \frac{I_{\text{HSMOD}}}{120 \mu\text{A}} \times 0.69$$

$$f(\text{HSIZE}) = 1 - \frac{V_{\text{HSIZE}}}{14.4 \text{ V}}$$

$$g(\text{HSIZE}, \text{HSMOD}) = 1 - \frac{V_{\text{HSIZE}} + V_{\text{HEHT}} \left(1 - \frac{V_{\text{HSIZE}}}{14.4 \text{ V}}\right)}{14.4 \text{ V}}$$

$$h(I_{\text{HREF}}) = \frac{I_{\text{HREF}}}{I_{\text{HREF}}|_{f=70\text{kHz}}}$$

Two different modes of operation can be chosen for the EW output waveform via control bit FHMULT:

1. Mode 1

Horizontal size is controlled via register HSIZE and causes a DC shift at the EWDRV output. The complete waveform is also multiplied internally by a signal proportional to the line frequency [which is detected via the current at HREF (pin 28)]. This mode is to be used for driving EW diode modulator stages which require a voltage proportional to the line frequency.

2. Mode 2

The EW drive waveform does not track with the line frequency. This mode is to be used for driving EW modulators which require a voltage independent of the line frequency.

I²C-bus autosync deflection controller for PC monitors

TDA4857PS

Output stage for asymmetric correction waveforms [ASCOR (pin 20)]

This output is designed as a voltage output for superimposed waveforms of vertical parabola and sawtooth. The amplitude and polarity of both signals can be changed via registers HPARAL and HPINBAL.

Application hint: The TDA4857PS offers two possibilities to control registers HPINBAL and HPARAL.

1. Control bit ACD = 1

The two registers now control the horizontal phase by means of internal modulation of the PLL2 horizontal phase control. The ASCOR output (pin 20) can be left unused, but it will always provide an output signal because the ASCOR output stage is not influenced by the control bit ACD.

2. Control bit ACD = 0

The internal modulation via PLL2 is disconnected. In order to obtain the required effect on the screen, pin ASCOR must now be fed to the DC amplifier which controls the DC shift of the horizontal deflection. This option is useful for applications which already use a DC shift transformer.

If the tube does not need HPINBAL and HPARAL, then pin ASCOR can be used for other purposes, i.e. for a simple dynamic convergence.

Dynamic focus section [FOCUS (pin 32)]

This section generates a complete drive signal for dynamic focus applications. The amplitude of the vertical parabola is independent of frequency and tracks with all vertical adjustments. The amplitude can be adjusted via register VFOCUS. FOCUS (pin 32) is designed as a voltage output for the vertical parabola.

B+ control function block

The B+ control function block of the TDA4857PS consists of an Operational Transconductance Amplifier (OTA), a voltage comparator, a flip-flop and a discharge circuit. This configuration allows easy applications for different B+ control concepts. See also Application Note AN96052: "B+ converter Topologies for Horizontal Deflection and EHT with TDA4855/58".

GENERAL DESCRIPTION

The non-inverting input of the OTA is connected internally to a high precision reference voltage. The inverting input is connected to BIN (pin 5). An internal clamping circuit limits the maximum positive output voltage of the OTA.

The output itself is connected to BOP (pin 3) and to the inverting input of the voltage comparator.

The non-inverting input of the voltage comparator can be accessed via BSENS (pin 4).

B+ drive pulses are generated by an internal flip-flop and fed to BDRV (pin 6) via an open-collector output stage.

This flip-flop is set at the rising edge of the signal at HDRV (pin 8). The falling edge of the output signal at BDRV has a defined delay of $t_{d(BDRV)}$ to the rising edge of the HDRV pulse (see Fig.21). When the voltage at BSENS exceeds the voltage at BOP, the voltage comparator output resets the flip-flop and, therefore, the open-collector stage at BDRV is floating again.

An internal discharge circuit allows a well defined discharge of capacitors at BSENS. BDRV is active at a LOW-level output voltage (see Figs 21 and 22), thus it requires an external inverting driver stage.

The B+ function block can be used for B+ deflection modulators in many different ways. Two popular application combinations are as follows:

- Boost converter in feedback mode (see Fig.21)

In this application the OTA is used as an error amplifier with a limited output voltage range. The flip-flop is set on the rising edge of the signal at HDRV. A reset will be generated when the voltage at BSENS, taken from the current sense resistor, exceeds the voltage at BOP.

If no reset is generated within a line period. The rising edge of the next HDRV pulse forces the flip-flop to reset. The flip-flop is set immediately after the voltage at BSENS has dropped below the threshold voltage

$V_{RESTART(BSENS)}$.

I²C-bus autosync deflection controller for PC monitors

TDA4857PS

- Buck converter in feed forward mode (see Fig.22)
 This application uses an external RC combination at BSENS to provide a pulse width which is independent from the horizontal frequency. The capacitor is charged via an external resistor and discharged by the internal discharge circuit. For normal operation the discharge circuit is activated when the flip-flop is reset by the internal voltage comparator. The capacitor will now be discharged with a constant current until the internally controlled stop level $V_{STOP(BSENS)}$ is reached. This level will be maintained until the rising edge of the next HDRV pulse sets the flip-flop again and disables the discharge circuit.

If no reset is generated within a line period, the rising edge of the next HDRV pulse automatically starts the discharge sequence and resets the flip-flop. When the voltage at BSENS reaches the threshold voltage $V_{RESTART(BSENS)}$, the discharge circuit will be disabled automatically and the flip-flop will be set immediately. This behaviour allows a definition of the maximum duty cycle of the B+ control drive pulse by the relationship of charge current to discharge current.

Supply voltage stabilizer, references, start-up procedures and protection functions

The TDA4857PS incorporates an internal supply voltage stabilizer to provide excellent stabilization for all internal references. An internal gap reference, especially designed for low-noise, is the reference for the internal horizontal and vertical supply voltages. All internal reference currents and drive current for the vertical output stage are derived from this voltage via external resistors.

If either the supply voltage is below 8.3 V or no data from the I²C-bus has been received after power-up, the internal soft start and protection functions do not allow any of those outputs [HDRV, BDRV, VOUT1, VOUT2 and HUNLOCK (see Fig.23)] to be active.

For supply voltages below 8.3 V the internal I²C-bus will not generate an acknowledge and the IC is in standby mode. This is because the internal protection circuit has generated a reset signal for the soft start register SOFTST. Above 8.3 V data is accepted and all registers can be loaded. If register SOFTST has received a set from the I²C-bus, the internal soft start procedure is released, which activates all mentioned outputs.

If during normal operation the supply voltage has dropped below 8.1 V, the protection mode is activated and HUNLOCK (pin 17) changes to the protection status and is floating. This can be detected by the microcontroller.

This protection mode has been implemented in order to protect the deflection stages and the picture tube during start-up, shut-down and fault conditions. This protection mode can be activated as shown in Table 3.

Table 3 Activation of protection mode

ACTIVATION	RESET
Low supply voltage at pin 10	increase supply voltage; reload registers; soft start via I ² C-bus
Power dip, below 8.1 V	reload registers; soft start via I ² C-bus
X-ray protection (pin 2) triggered, XSEL (pin 9) is open-circuit or connected to ground	reload registers; soft start via I ² C-bus
X-ray protection (pin 2) triggered, XSEL (pin 9) connected to V _{CC} via an external resistor	switch V _{CC} off and on again, reload registers; soft start via I ² C-bus
HPLL2 (pin 30) externally pulled to ground	release pin 30

When the protection mode is active, several pins of the TDA4857PS are forced into a defined state:

- HDRV (horizontal driver output) is floating
- BDRV (B+ control driver output) is floating
- HUNLOCK (indicates, that the frequency-to-voltage converter is out of lock) is floating (HIGH via external pull-up resistor)
- CLBL provides a continuous blanking signal
- VOUT1 and VOUT2 (vertical outputs) are floating
- The capacitor at HPLL2 is discharged.

If the soft start procedure is activated via the I²C-bus, all of these actions will be performed in a well defined sequence (see Figs 23 and 24).

I²C-bus autosync deflection controller for PC monitors

TDA4857PS

Notes

1. For duration of vertical blanking pulse see subheading 'Vertical oscillator [oscillator frequency in application without adjustment of free-running frequency $f_{fr(V)}$]'.
2. Continuous blanking at CLBL (pin 16) will be activated, if one of the following conditions is true:
 - a) No horizontal flyback pulses at HFLB (pin 1) within a line
 - b) X-ray protection is triggered
 - c) Voltage at HPLL2 (pin 30) is low during soft start
 - d) Supply voltage at V_{CC} (pin 10) is low
 - e) PLL1 unlocked while frequency-locked loop is in search mode.
3. Oscillator frequency is f_{min} when no sync input signal is present (continuous blanking at pins 16 and 17).
4. Loading of HPLL1 (pin 26) is not allowed.
5. Voltage at HPLL1 (pin 26) is fed to HBUF (pin 27) via a buffer. Disturbances caused by horizontal sync are removed by an internal sample-and-hold circuit.
6. All vertical and EW adjustments in accordance with note 8, but VSIZE = 80% (register VSIZE = 63 and control bit VOVSCN = 0).
7. Value of resistor at VREF (pin 23) may not be changed.
8. All vertical and EW adjustments are specified at nominal vertical settings; unless otherwise specified, which means:
 - a) VSIZE = 100% (register VSIZE = 127 and control bit VOVSCN = 0)
 - b) VSMOD = 0 (no EHT compensation)
 - c) VPOS centred (register VPOS = X and control bit VPC = 1)
 - d) VLIN = 0 (register VLIN = X and control bit VSC = 1)
 - e) VLINBAL = 0 (register VLINBAL = X and control bit VLC = 1)
 - f) FHMULT = 0
 - g) HPARAL = 0 (register HPARAL = X and control bit HPC = 1)
 - h) HPINBAL = 0 (register HPINBAL = X and control bit HBC = 1)
 - i) Vertical oscillator synchronized
 - j) HSIZE = 255.
9. The output signal at EWDRV (pin 11) may consist of horizontal pincushion + corner correction + DC shift + trapezium correction. If the control bit VOVSCN is set, and the VPOS adjustment is set to an extreme value, the tip of the parabola may be clipped at the upper limit of the EWDRV output voltage range. The waveform of corner correction will clip if the vertical sawtooth adjustment exceeds 110% of the nominal setting.
10. If f_H tracking is enabled, the amplitude of the complete EWDRV output signal (horizontal pincushion + corner correction + DC shift + trapezium) will be changed proportional to I_{HREF} . The EWDRV low level of 1.2 V remains fixed.
11. First pole of transconductance amplifier is 5 MHz without external capacitor (will become the second pole, if the OTA operates as an integrator).
12. Open-loop gain is $\frac{V_{BOP}}{V_{BIN}}$ at $f = 0$ with no resistive load and $C_{BOP} = 10$ nF [from BOP (pin 3) to GND].

TDA4857PS

I²C-BUS PROTOCOL

I²C-bus data format

S ⁽¹⁾	SLAVE ADDRESS ⁽²⁾	A ⁽³⁾	SUBADDRESS ⁽⁴⁾	A ⁽³⁾	DATA ⁽⁵⁾	A ⁽³⁾	P ⁽⁶⁾
------------------	------------------------------	------------------	---------------------------	------------------	---------------------	------------------	------------------

Notes

1. S = START condition.
2. SLAVE ADDRESS (MAD) = 1000 1100.
3. A = acknowledge, generated by the slave. No acknowledge, if the supply voltage is below 8.3 V for start-up and 8.1 V for shut-down procedure.
4. SUBADDRESS (SAD).
5. DATA, if more than 1 byte of DATA is transmitted, then **no** auto-increment of the significant subaddress is performed.
6. P = STOP condition.

It should be noted that clock pulses according to the 400 kHz specification are accepted for 3.3 and 5 V applications (reference level = 1.8 V). Default register values after power-up are random. All registers have to be preset via software before the soft start is enabled.

Important: If the register contents are changed during the vertical scan, this might result in a visible interference on the screen. The cause for this interference is the abrupt change in picture geometry which takes effect at random locations within the visible picture.

To avoid this kind of interference, the adjustment of the critical geometry parameters HSIZE, HPOS, VSIZE and VPOS should be synchronized with the vertical flyback. This should be done in such a way that the adjustment change takes effect during the vertical blanking time (see Fig.17).

For very slow I²C-bus interfaces, it might be necessary to delay the transmission of the last byte (or only the last bit) of an I²C-bus message until the start of the vertical sync or vertical blanking.

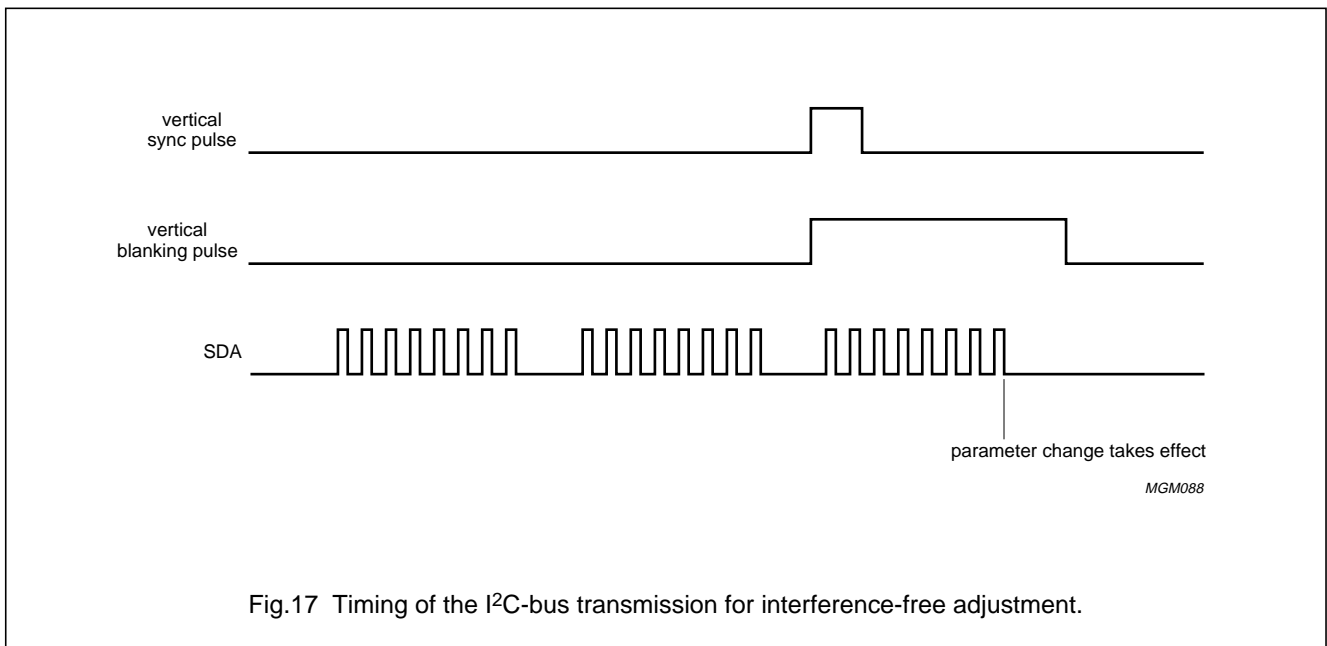

Fig.17 Timing of the I²C-bus transmission for interference-free adjustment.

Notes

1. X = don't care.
2. # = this bit is occupied by another function. If the register is addressed, the bit values for both functions must be transferred.

I²C-bus autosync deflection controller for PC monitors

TDA4857PS

Start-up procedure

V_{CC} < 8.3 V:

- As long as the supply voltage is too low for correct operation, the IC will give no acknowledge due to internal Power-on reset (POR)
- Supply current is 9 mA or less.

V_{CC} > 8.3 V:

- The internal POR has ended and the IC is in standby mode
- Control bits STDBY and SOFTST are reset to their start values
- All other register contents are random
- Pin HUNLOCK is at HIGH-level.

Setting control bit STDBY = 0:

- Enables internal power supply
- Supply current increases from 9 to 70 mA
- When V_{CC} < 8.6 V register SOFTST cannot be set by the I²C-bus
- Output stages are disabled, except the vertical output
- Pin HUNLOCK is at HIGH-level.

Setting all registers to defined values:

- Due to the hardware configuration of the IC (no auto-increment) any register setting needs a complete 3-byte I²C-bus data transfer as follows: START - IC address - subaddress - data - STOP.

Setting control bit SOFTST = 1:

- Before starting the soft-start sequence a delay of minimum 80 ms is necessary to obtain correct function of the horizontal drive
- HDRV duty cycle increases
- BDRV duty cycle increases
- PLL1 and PLL2 are enabled.

IC in full operation:

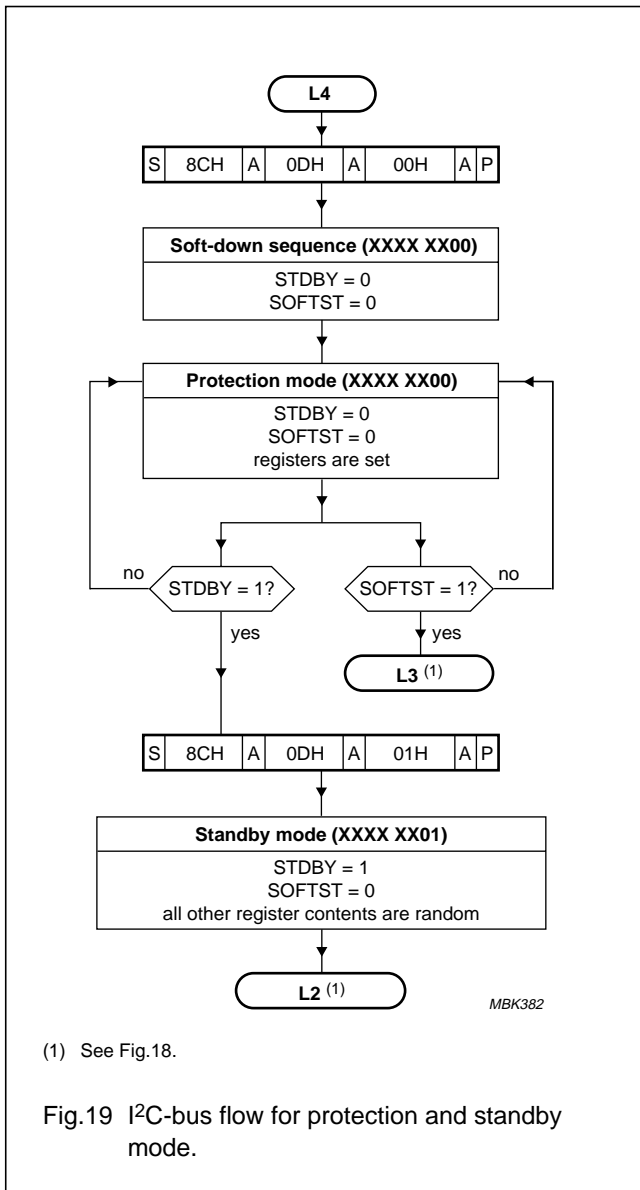

- Pin HUNLOCK is at LOW-level when PLL1 is locked
- Any change of the register content will result in immediate change of the output behaviour
- Setting control bit SOFTST = 0 is the only way (except power-down via pin V_{CC}) to leave the operating mode.

Soft-down sequence:

- See L4 of Fig.19 for starting the soft-down sequence.

I²C-bus autosync deflection controller for PC monitors

TDA4857PS

Protection and standby mode

Soft-down sequence:

- Start the sequence by setting control bit SOFTST = 0
- BDRV duty cycle decreases
- HDRV duty cycle decreases.

Protection mode:

- Pins HDRV and BDRV are floating
- Continuous blanking at pin CLBL is active
- Pin HUNLOCK is floating
- PLL1 and PLL2 are disabled
- Register contents are kept in internal memory.

Protection mode can be left by 3 ways:

1. Entering standby mode by setting control bit SOFTST = 0 and control bit STDBY = 1
2. Starting the soft-start sequence by setting control bit SOFTST = 1 (bit STDBY = don't care); see L3 of Fig.18 for continuation
3. Decreasing the supply voltage below 8.1 V.

Standby mode:

- Set control bit STDBY = 1
- Driver outputs are floating (same as protection mode)
- Supply current is 9 mA
- Only the I²C-bus and protection circuits are operative
- Contents of all registers except the value of bit STDBY and bit SOFTST are lost
- See L2 of Fig.18 for continuation.

I²C-bus autosync deflection controller for PC monitors

TDA4857PS

Power-down mode

Power dip of $V_{CC} < 8.6\text{ V}$:

- The soft-down sequence is started first.
- Then the soft-start sequence is generated internally.

Power dip of $V_{CC} < 8.1\text{ V}$ or V_{CC} shut-down:

- This function is independent from the operating mode, so it works under any condition.
- All driver outputs are immediately disabled
- IC enters standby mode.

PLL2 soft start sequence and PLL2 soft-down sequence

a. PLL2 soft start sequence, via the I²C-bus, if V_{CC} > 8.6 V.

b. PLL2 soft-down sequence, via the I²C-bus, if V_{CC} > 8.6 V.

(1) HDRV, BDRV, VOUT2 and VOUT1 are floating for V_{CC} < 8.6 V.

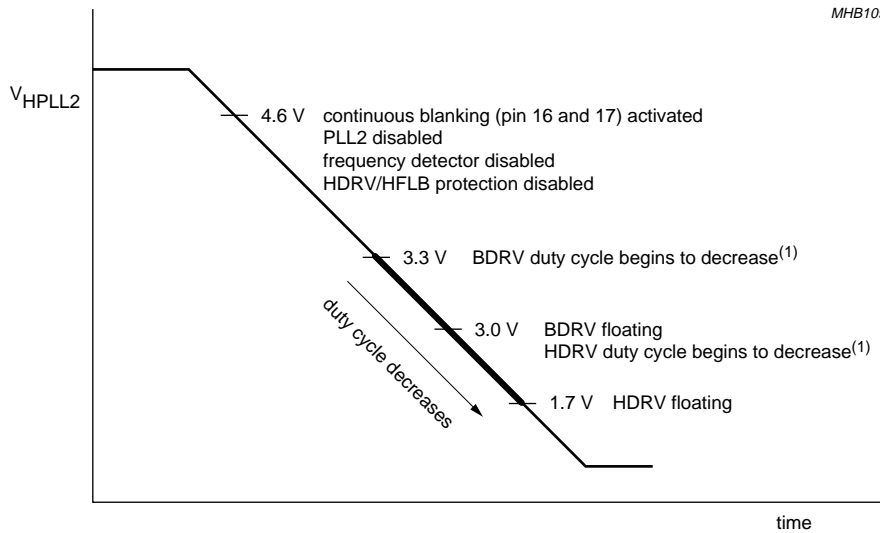

Fig.24 PLL2 soft start sequence and PLL2 soft-down sequence via the I²C-bus.

I²C-bus autosync deflection controller for PC monitors

TDA4857PS

a. PLL2 soft start sequence by external DC current, if $V_{CC} > 8.6$ V.

b. PLL2 soft-down sequence by external DC current, if $V_{CC} > 8.6$ V.

(1) HDRV, BDRV, VOUT2 and VOUT1 are floating for $V_{CC} < 8.6$ V.

Fig.25 PLL2 soft start sequence and PLL2 soft-down sequence by external DC current.

I²C-bus autosync deflection controller for PC monitors

TDA4857PS

Fig.26 Activation of the soft-down sequence via pin XRAY.

Vertical linearity error

- (1) $I_{VOUT} = I_{VOUT1} - I_{VOUT2}$.
- (2) $I_1 = I_{VOUT}$ at $V_{VCAP} = 1.9$ V.
- (3) $I_2 = I_{VOUT}$ at $V_{VCAP} = 2.6$ V.
- (4) $I_3 = I_{VOUT}$ at $V_{VCAP} = 3.3$ V.

Which means: $I_0 = \frac{I_1 - I_3}{2}$

Vertical linearity error = $1 - \max\left(\frac{I_1 - I_2}{I_0} \text{ or } \frac{I_2 - I_3}{I_0}\right)$

Fig.27 Definition of vertical linearity error.

Electrostatic discharge (ESD) protection

I²C-bus autosync deflection controller for PC monitors

TDA4857PS

PACKAGE OUTLINE

SDIP32: plastic shrink dual in-line package; 32 leads (400 mil)

SOT232-1

DIMENSIONS (mm are the original dimensions)

UNIT	A max.	A ₁ min.	A ₂ max.	b	b ₁	c	D ⁽¹⁾	E ⁽¹⁾	e	e ₁	L	M _E	M _H	w	Z ⁽¹⁾ max.
mm	4.7	0.51	3.8	1.3 0.8	0.53 0.40	0.32 0.23	29.4 28.5	9.1 8.7	1.778	10.16	3.2 2.8	10.7 10.2	12.2 10.5	0.18	1.6

Note

1. Plastic or metal protrusions of 0.25 mm maximum per side are not included.

SOLDERING

Introduction to soldering through-hole mount packages

This text gives a brief insight to wave, dip and manual soldering. A more in-depth account of soldering ICs can be found in our *"Data Handbook IC26; Integrated Circuit Packages"* (document order number 9398 652 90011).

Wave soldering is the preferred method for mounting of through-hole mount IC packages on a printed-circuit board.

Soldering by dipping or by solder wave

The maximum permissible temperature of the solder is 260 °C; solder at this temperature must not be in contact with the joints for more than 5 seconds.

The total contact time of successive solder waves must not exceed 5 seconds.

The device may be mounted up to the seating plane, but the temperature of the plastic body must not exceed the specified maximum storage temperature ($T_{stg(max)}$). If the printed-circuit board has been pre-heated, forced cooling may be necessary immediately after soldering to keep the temperature within the permissible limit.

Manual soldering

Apply the soldering iron (24 V or less) to the lead(s) of the package, either below the seating plane or not more than 2 mm above it. If the temperature of the soldering iron bit is less than 300 °C it may remain in contact for up to 10 seconds. If the bit temperature is between 300 and 400 °C, contact may be up to 5 seconds.

Suitability of through-hole mount IC packages for dipping and wave soldering methods

PACKAGE	SOLDERING METHOD	
	DIPPING	WAVE
DBS, DIP, HDIP, SDIP, SIL	suitable	suitable ⁽¹⁾

Note

- For SDIP packages, the longitudinal axis must be parallel to the transport direction of the printed-circuit board.
